INSTANT CENTERS OF VELOCITY (Section 6.4 in Norton) Instant Center - denotes the center of rotation of a body at an instant in time. The center of rotation doesn't necessarily have to lie within the link itself. 1. It is a point in one body about which some other body is permanently or instantaneously rotating about. 2.

INSTANT CENTERS OF VELOCITY (Section 6

Rigid body: $\frac{3}{4}$ A point of a rigid body whose velocity is zero at a given instant is called instantaneous center.

Instant Centers Of Velocity Section The instant center is also called the instantaneous center of zero velocity (IC). It lies on an imaginary axis of zero velocity, about which the body appears to rotate at a given instant. This axis is always perpendicular to the plane of motion.

The instant center is also called the instantaneous center of zero velocity (IC). It lies on an imaginary axis of zero velocity, about which the body appears to rotate at a given instant. This axis is always perpendicular to the plane of motion. There are three basic cases to consider when solving problems using the instant center approach.

INSTANTANEOUS CENTER OF ZERO VELOCITY (Section 16-6) For any body undergoing planar motion, there always exists a point in the plane of motion at which the velocity is instantaneously zero (if it is rigidly connected to the body). This point is called the instantaneous center (IC) of zero velocity. It may or may not lie on the body!

The instant center of rotation, also called instantaneous velocity center, or also instantaneous center or instant center, is the point fixed to a body undergoing planar movement that has zero velocity at a particular instant of time. At this instant, the velocity vectors of the other points in the body generate a circular field around this point which is identical to what is generated by a pure rotation. Planar movement of a body is often described using a plane figure moving in a two-dimension

To measure velocity, you might use a speedometer in combination with a compass. Sometimes, you are interested in the average velocity over a period of time instead of velocity at a particular instant. Therefore, we define the average velocity of an object as displacement (distance in a particular direction) divided by time.

The most obvious instant center of velocities, or simply the instant center (IC), between two links that are pinned to each other is the point at the center of the pin joint. For example, the center of the pin joint between links i and j can be viewed as two coinciding points, P_i on link i and P_j on link j , that have the same velocities. The instant center between these two links is denoted as $I_{i,j}$ or I

It may or may not lie on the body! If the location of this point can be determined, the velocity analysis can be simplified because the body appears to rotate
