During the last 20 years several less-invasive anterior approaches to the lumbar spine have become standard, including the extreme lateral lumbar interbody fusion. Although it is associated with a lower risk of vascular injury compared with anterior midline approaches, neuromonitoring is considered mandatory to avoid neurologic complications. Interestingly, despite neuromonitoring, the reported risk of neurologic deficits with the extreme lateral transpsoas approach is greater than observed ...

Lateral lumbar interbody fusion is a minimally invasive technique first described by Ozgur et al. 1). LLIF allows the surgeon to access the intervertebral space via a minimally invasive direct lateral approach through the psoas muscle. The advantage of LLIF over the traditional anterior approach is the avoidance of exposure of the abdominal viscera, large vessels, and sympathetic plexus.

Anterior lumbar interbody fusion represents another alternative to a 360-degree spinal fusion but requires a separate anterior approach. In 1982, with the rationale of offering a secure fusion in a one-stage operation, Harms and Rolinger pioneered a modified PLIF technique called transforaminal lumbar interbody fusion (TLIF). Compared with the more traditional techniques, it provides several advantages by accessing the spinal canal and disc via a path that runs through the far-lateral ...

BACKGROUND: Anterior, direct lateral, and transforaminal lumbar interbody fusions (ALIF, DLIF, and TLIF) are usually combined with posterior fixation to treat degenerative spinal diseases. Outcomes of ALIF, TLIF, or DLIF combined with a new wedge-shaped interfacet cage plate have not been reported.
